

CISS433: Python Programming

Lecture 19: More Operators

Yihsiang Liow

Agenda

- ♦ More on operators
- ♦ First introduction to iterators and exceptions
 - ♦ We will cover exceptions in greater detail later – it's an extremely important concept
 - ♦ We will probably not cover iterators in great detail. You'll find more on that in CISS350.

Operator Overloading

- Recall that in a class `C` we can define method `__add__(self, x)` and when you execute

$$z = x + y$$
 where `x`, `y` are `C`-objects, then `x+y` is translated to `C.__add__(x, y)`
- `__add__` defines a new meaning for `+`
- We say that we are overloading `+`

Methods for Operator Overloading

<code>__add__</code>	<code>x+y</code>	<code>C.__add__(x,y)</code>
<code>__radd__</code>	<code>a+x</code>	<code>C.__radd__(x,a)</code>
<code>__iadd__</code>	<code>x+=y</code>	<code>C.__iadd__(x,y)</code>
[or <code>__add__</code> if <code>__iadd__</code> not defined]		

and other arithmetic operators

<code>__or__</code>	<code>x y</code>	<code>C.__or__(x,y)</code>
<code>__call__</code>	<code>x(arg)</code>	<code>C.__call__(x,arg)</code>
[Arbitrary number of arguments]		
<code>__len__</code>	<code>len(x)</code>	<code>C.__len__(x)</code>

Methods for Overloading Operators

<code>__getitem__</code>	<code>z = x[i]</code>	<code>z = C.__getitem__(x,i)</code>
<code>__setitem__</code>	<code>x[i] = z</code>	<code>C.__setitem__(x,i,z)</code>
<code>__cmp__</code>	<code>x==y, x<=y</code>	<code>C.__cmp__(x,y)</code>
<code>__lt__</code>	<code>x<y</code>	<code>C.__lt__(x,y)</code> [or <code>__cmp__</code> if <code>__lt__</code> not defined]
<code>__eq__</code>	<code>x==y</code>	<code>C.__eq__(x,y)</code> [or <code>__cmp__</code> if <code>__lt__</code> not defined]
<code>__getattr__</code>	<code>z = x.attr</code>	<code>C.__getattr__(x,attr)</code>
<code>__setattr__</code>	<code>x.attr = z</code>	<code>C.__setattr__(x,attr,z)</code>

__getitem__ and for-loop

```
class C:

    def __init__(self):
        self.__attr = [1,2,3]
        pass

    def __getitem__(self,i):
        print("    __getitem__: i =", i)
        return self.__attr[i]

c = C()
for x in c:
    print(x)
```

- Can you tell me what's happening here?
- The `in` operator and list comprehension uses `__getitem__` too

__iter__ and for-loop

```
class C:
```

```
    def __init__(self):
        self.__index = None
        self.__list = [5,4,3,2,1]
```

```
    def __iter__(self):
        self.__index = -1
        return self
```

```
    def __next__(self):
        if self.__index >= len(self.__list)-1:
            raise StopIteration
        self.__index += 1
        return self.__list[self.__index]
```

This is an exception

```
c = C()
for x in c: print(x)
```

If **__iter__** not found,
 use **__getitem__**

__call__

- ♦ The `__call__` method makes your objects look like functions.

```
class factorial:

    def __init__(self):
        pass

    def __call__(self,n):
        p = 1
        for i in range(1,n+1): p *= i
        return p

f = factorial()
print f(5)
```

__call__

- ♦ Rewrite the factorial function so that it **keeps** it computation of factorials So when f(5) is called again, it returns the factorial of 5 that was previously saved.

`__del__`

- In some OO languages, besides the constructor, there is a destructor
- The aim of the destructor is to perform some clean up operation before the object is destroyed
- For Python, memory is reclaimed automatically so usually the destructor is not defined
- If you want to perform some operation before the object is destroyed, then define the `__del__` method
